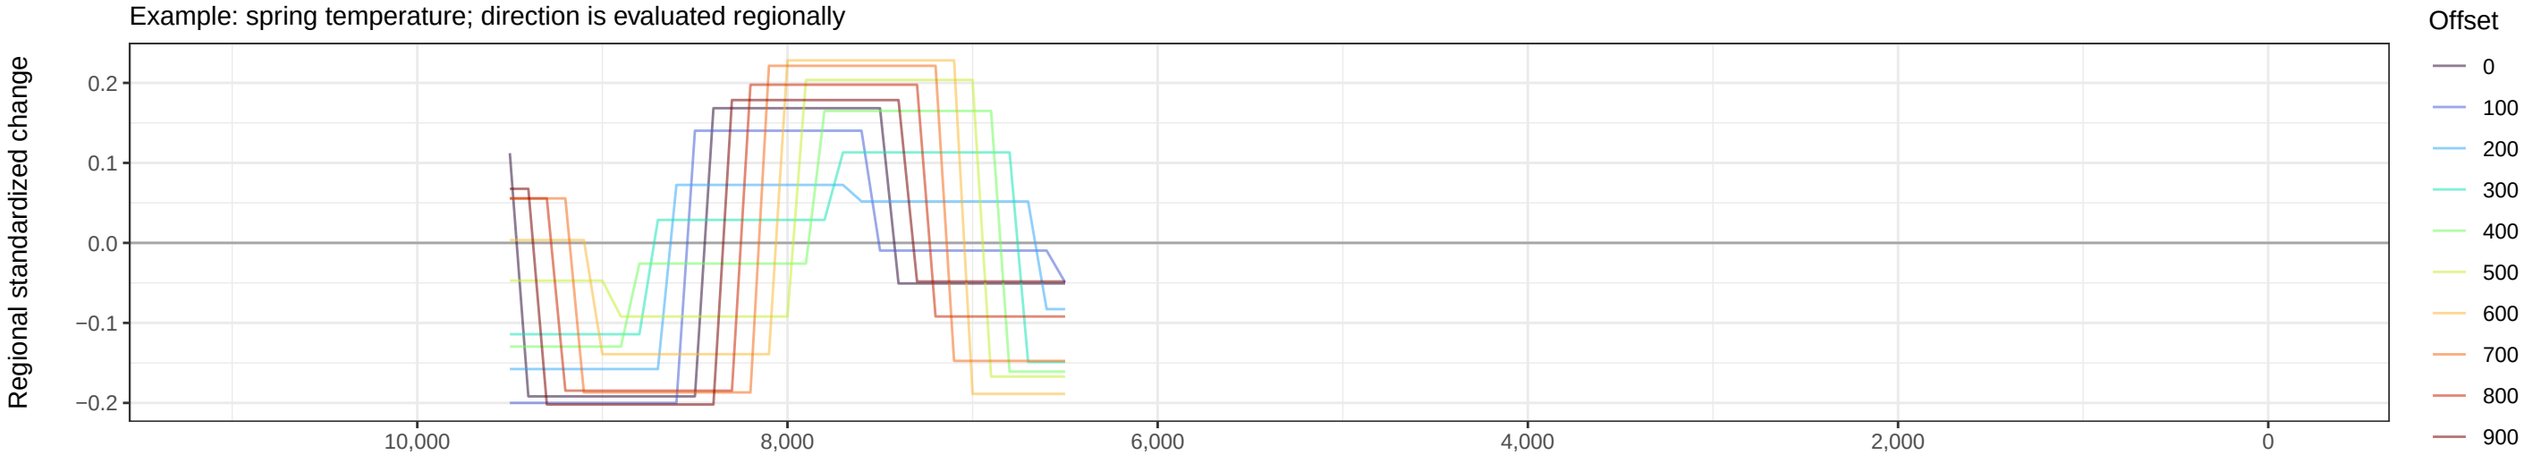
Worked example: unified Holocene climate eras

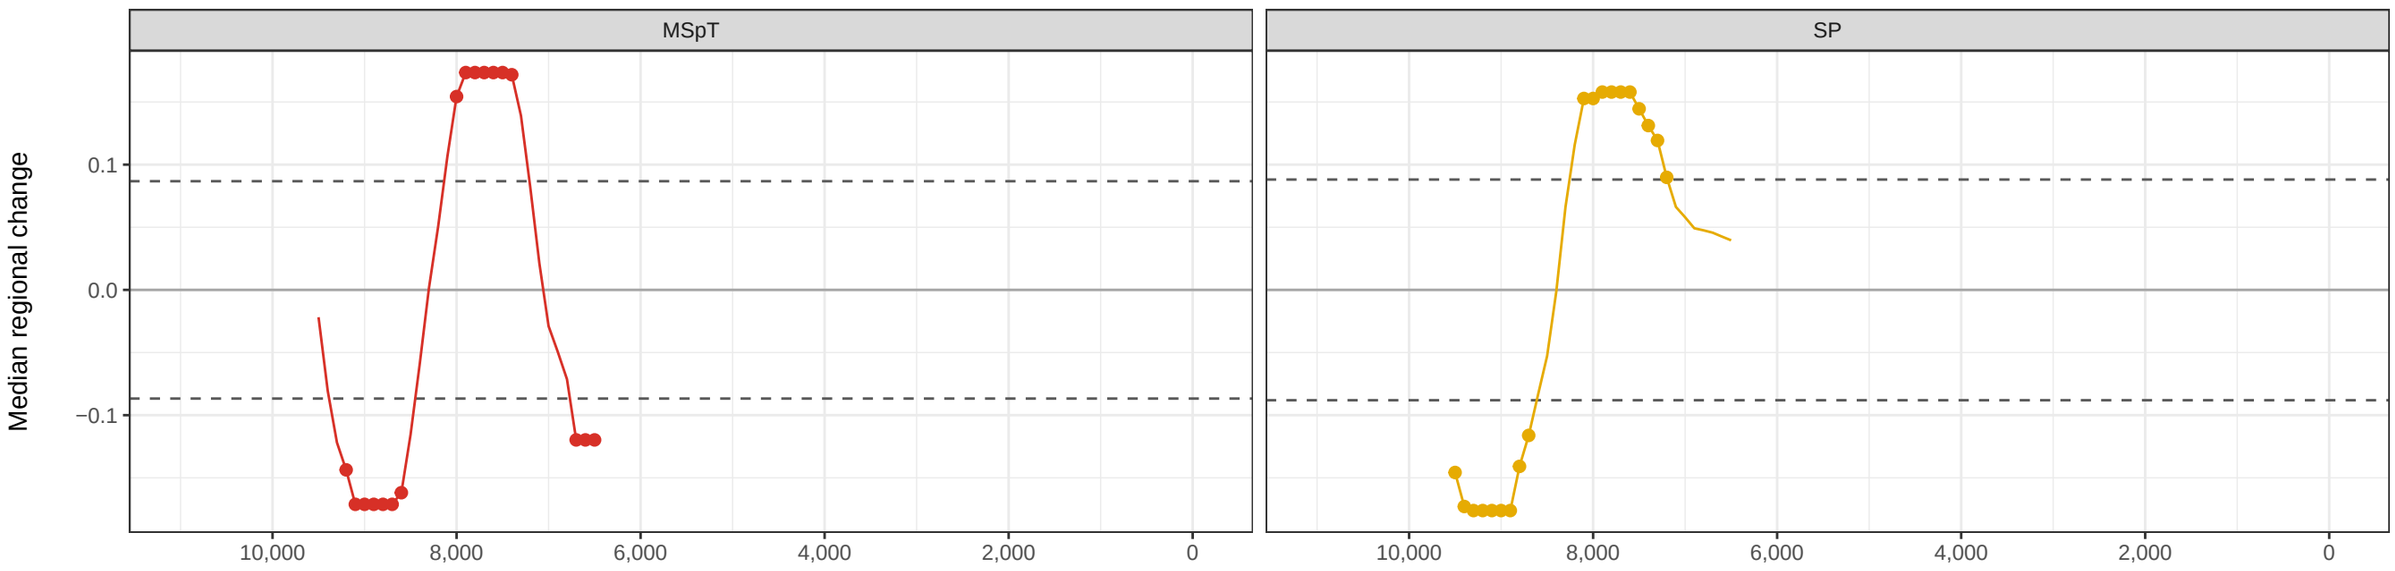
1. Ten phases expose placement sensitivity

Example: spring temperature; direction is evaluated regionally



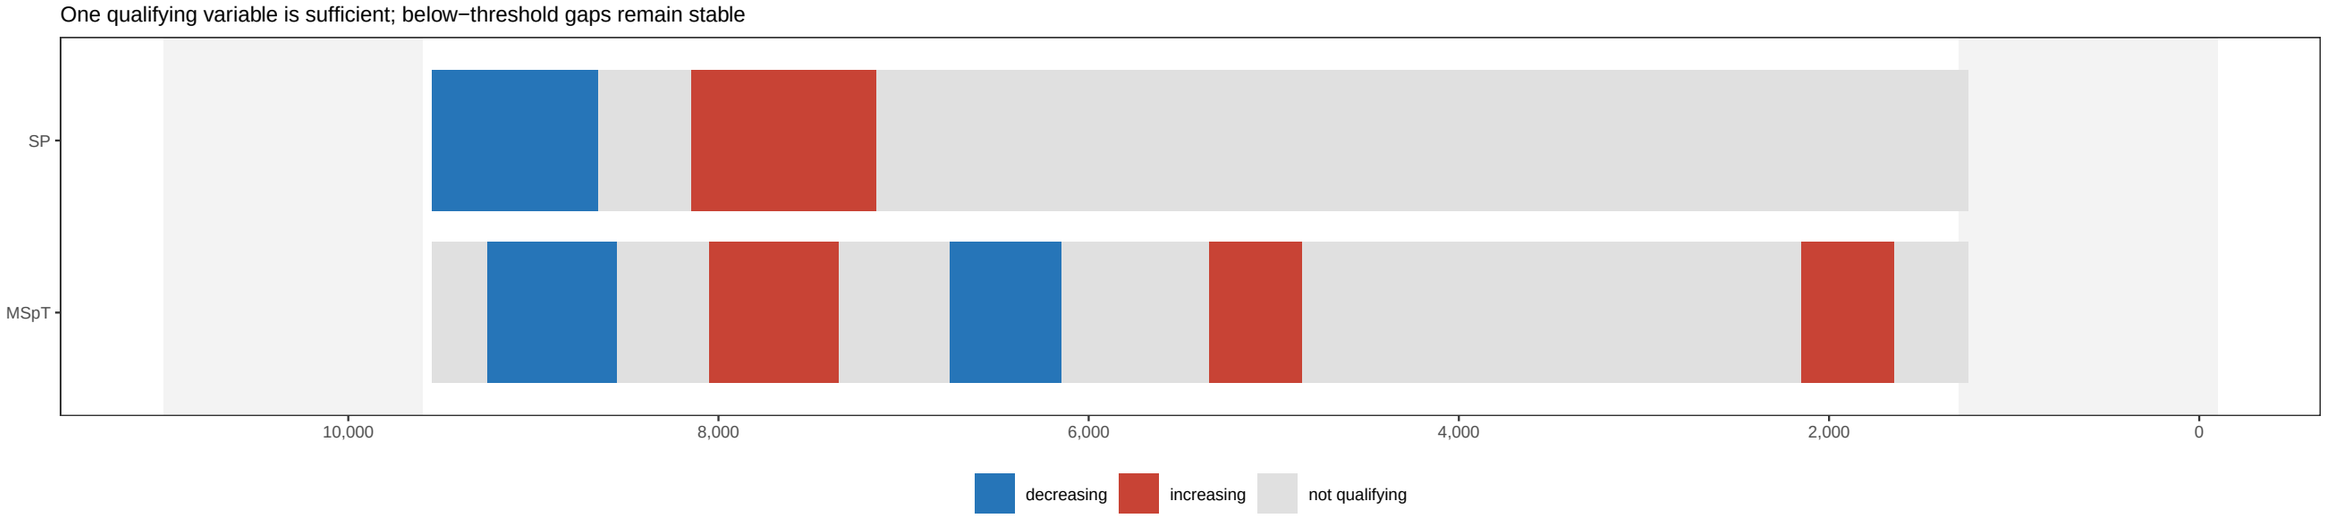
2. Apply each variable's 50%−of−maximum threshold

A filled cell also needs >=8/10 phases in the regional direction



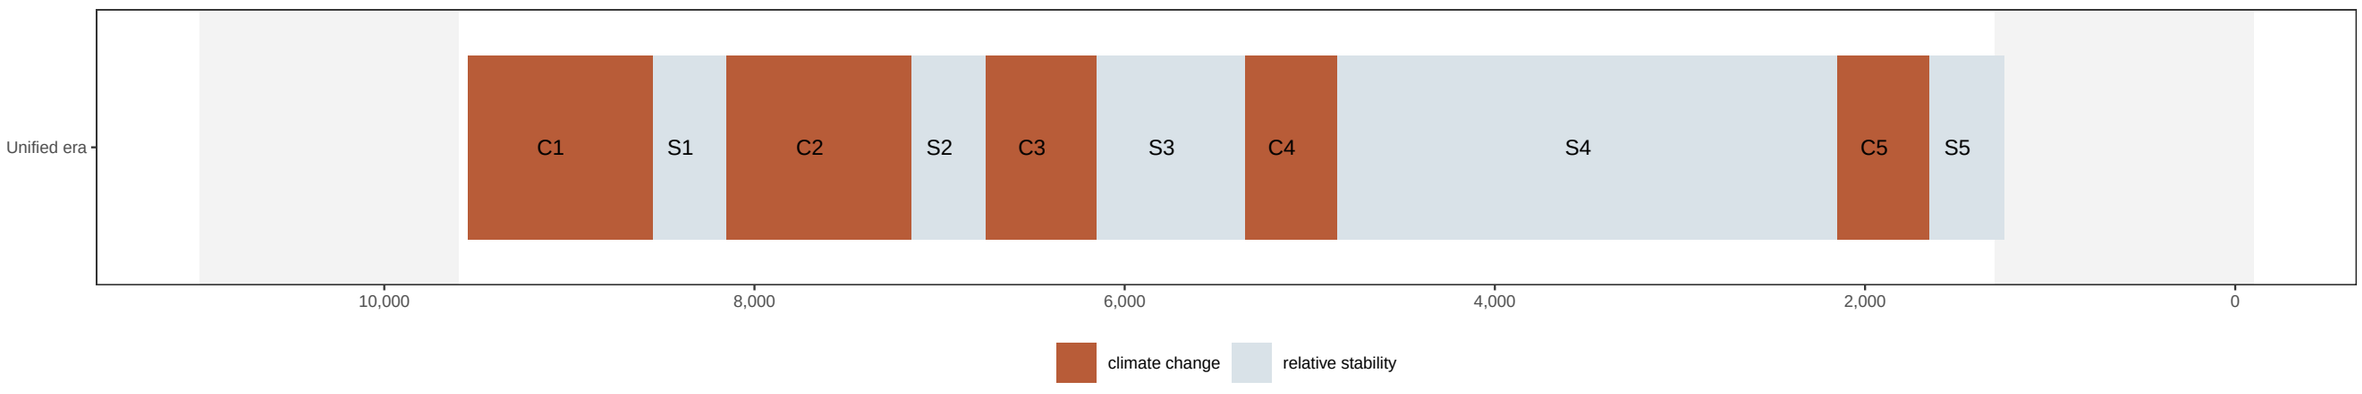
3. Keep direction, then take the any−variable union

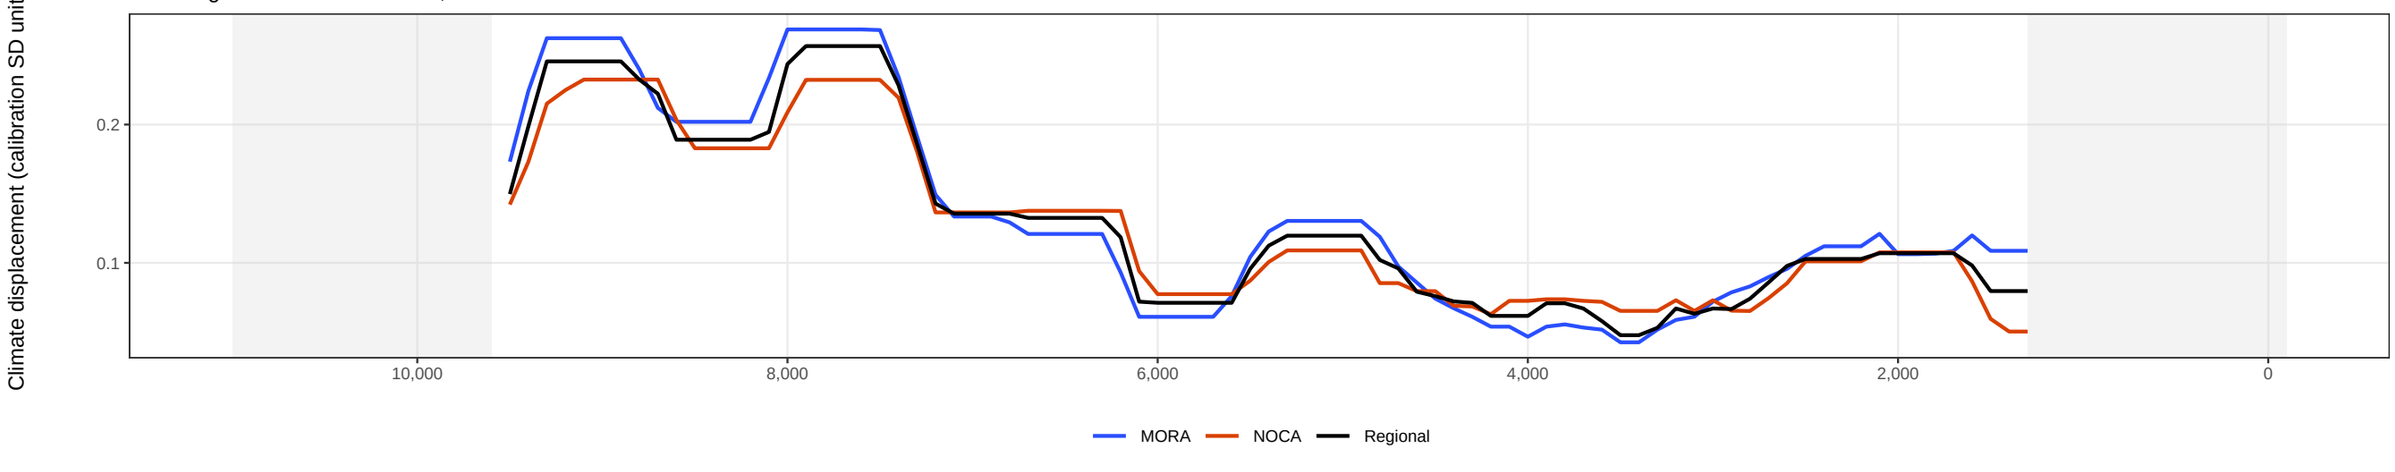
One qualifying variable is sufficient; below−threshold gaps remain stable



4. Merge only adjacent cells and number CC/S eras

No site−direction veto, transition state, forward extension, or gap bridging



5. Composite magnitude is a visual cross−check


It is unsigned and unthresholded, so it never selects direction or eras
