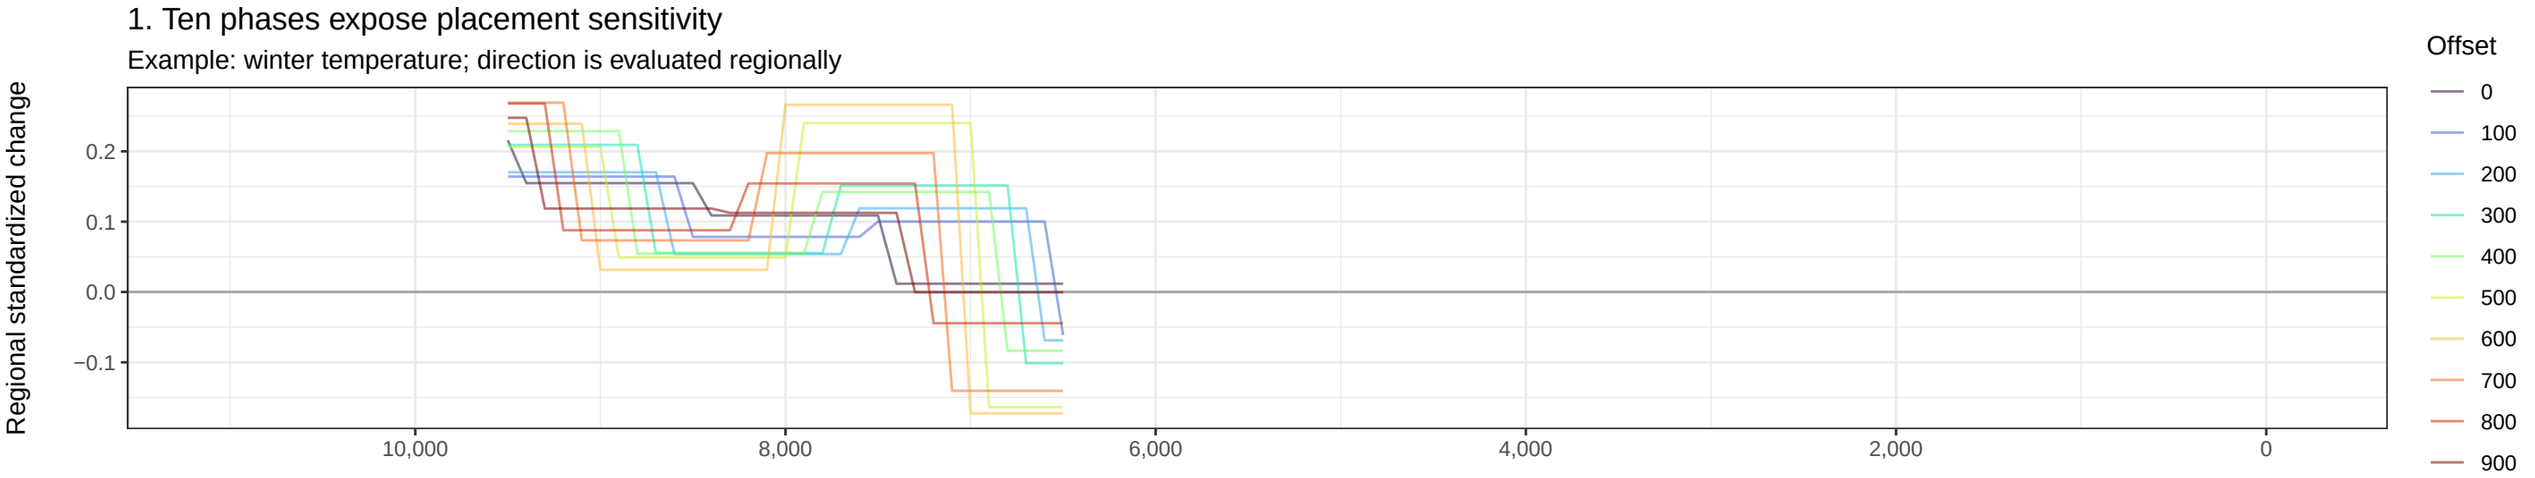
Worked example: unified Holocene climate eras and fire periods

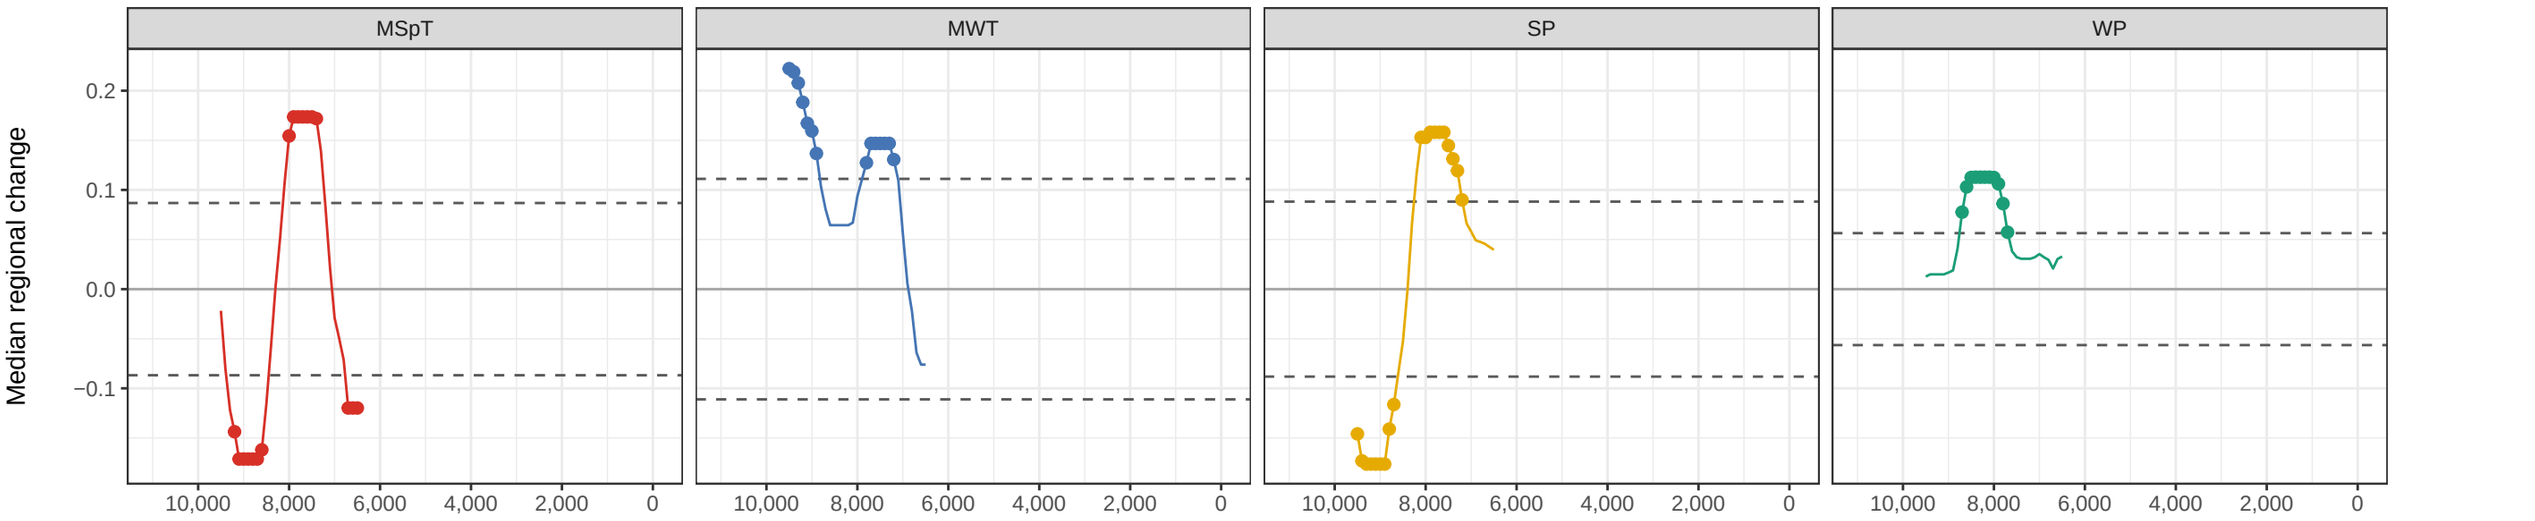
1. Ten phases expose placement sensitivity

Example: winter temperature; direction is evaluated regionally



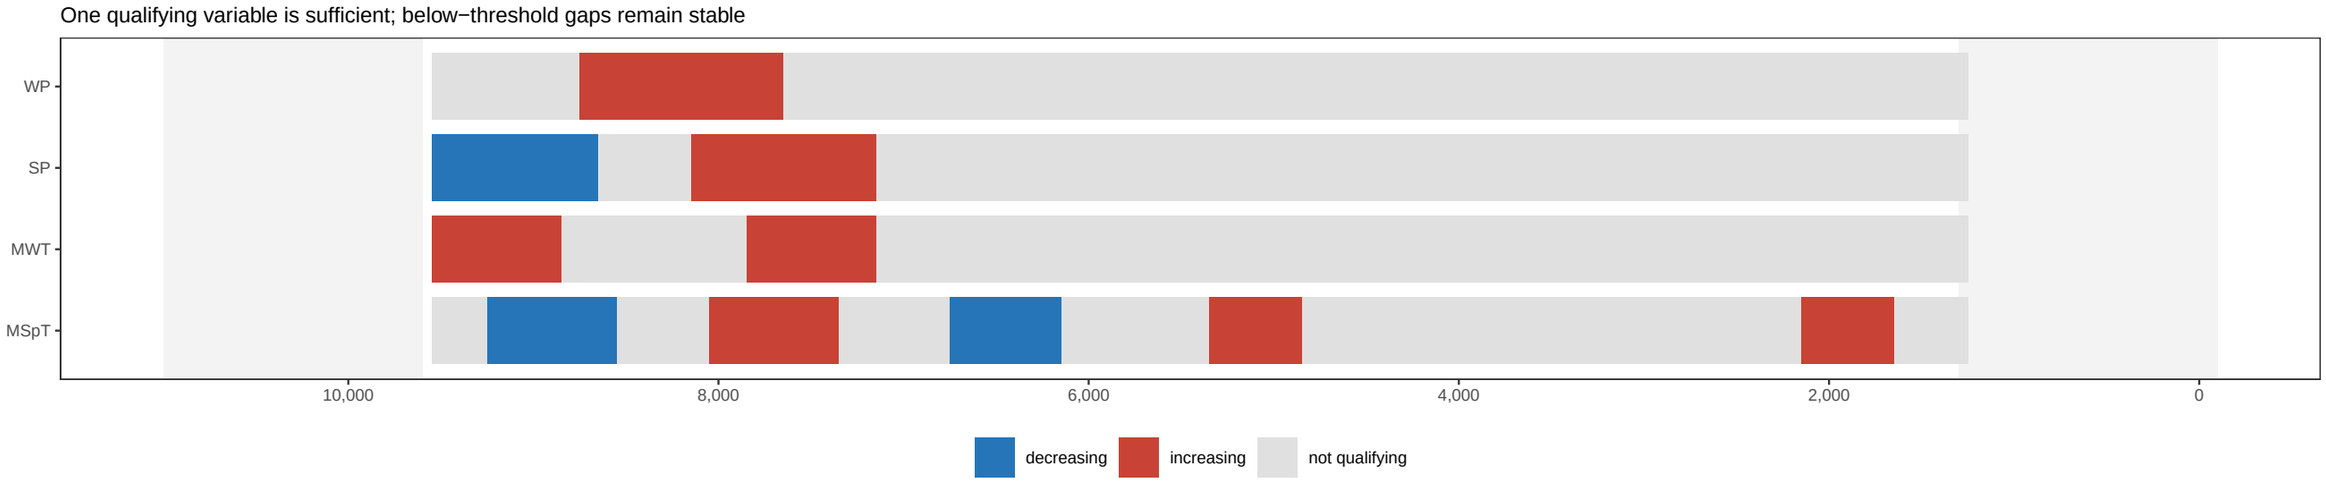
2. Apply each variable's 50%−of−maximum threshold

A filled cell also needs >=8/10 phases in the regional direction



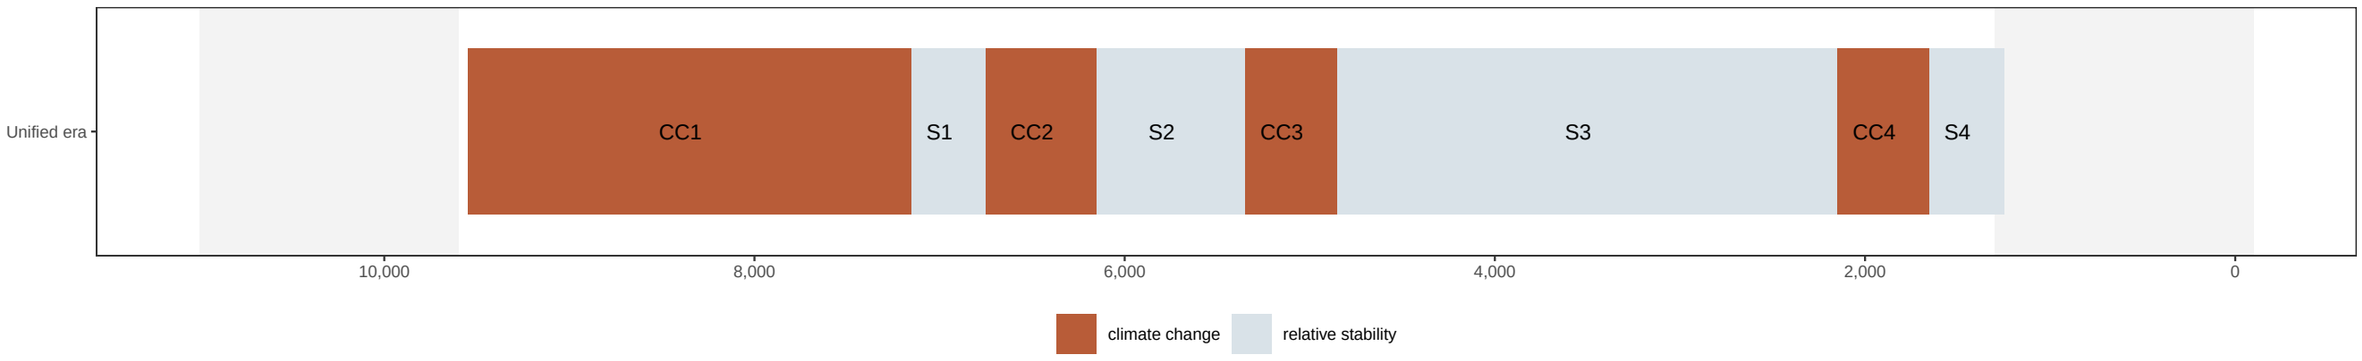
3. Keep direction, then take the any−variable union

One qualifying variable is sufficient; below−threshold gaps remain stable



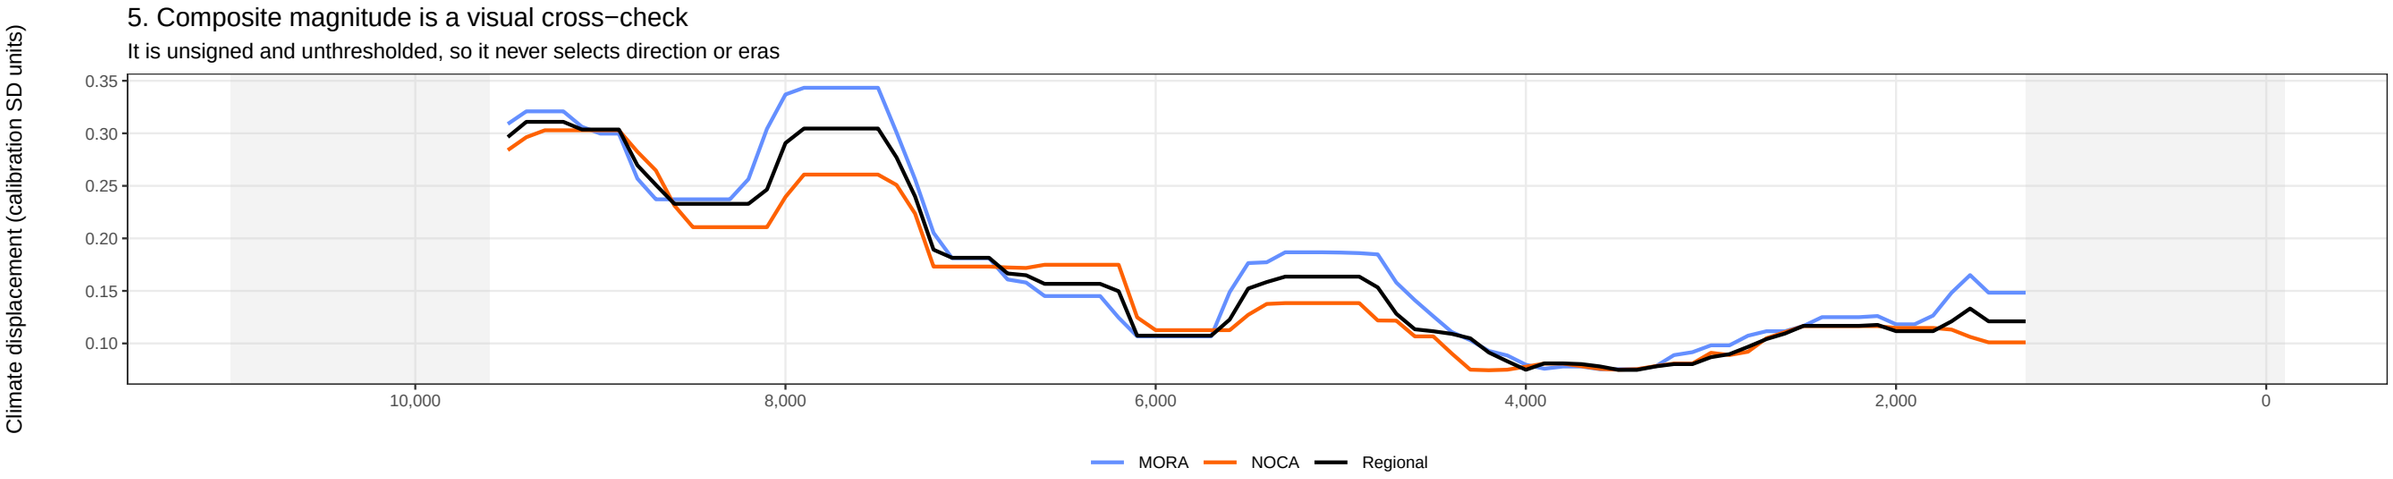
4. Merge only adjacent cells and number CC/S eras

No site−direction veto, transition state, forward extension, or gap bridging



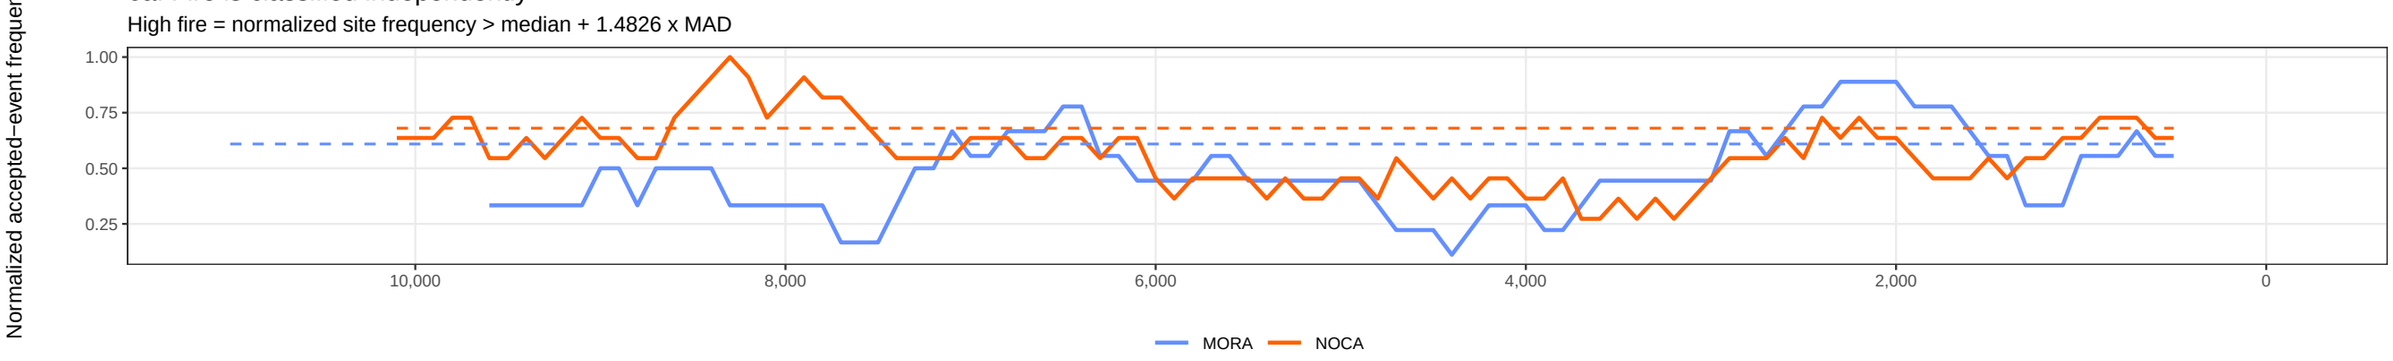
5. Composite magnitude is a visual cross−check

It is unsigned and unthresholded, so it never selects direction or eras



6a. Fire is classified independently

High fire = normalized site frequency > median + 1.4826 x MAD



6b. Every contiguous run is retained

Frequency selects periods; strength/background are corroboration only
